## Songbirds, Raptors Studied at Idaho Bird Observatory

Every fall, tens of thousands of migratory birds fly along the Boise Ridge on their journey southward, a seasonal ritual that provides researchers at Boise State's Idaho Bird Observatory (IBO) with unique opportunities for study.

Founded in 1993, IBO is a research unit of the university devoted to monitoring migrating raptors and songbirds and educating the public about their greater ecological significance. Boise State is the only university in the nation that offers a master's degree in raptor biology.

"Because raptors are top-level predators, they are indicators of overall environmental health," said IBO director Greg Kaltenecker. "All migratory birds are good indicators because they depend on many different habitats."

The Boise Ridge is a crucial link in a chain of breeding and wintering areas. It was deemed so crucial, in fact, that it was designated an "Important Bird Area" of international significance by the National Audubon Society. During the 2008 field season, more than 5,000 songbirds were captured, examined, banded and released by IBO researchers at field sites near Lucky Peak, including the first varied thrush ever captured. Nearly 6,000 raptors were counted and close to

1,000 captured and quickly released, including hawks, eagles and owls.

The 2008 totals for raptors and songbirds were generally consistent with long-term data, said IBO research director Jay Carlisle. The results of previous annual counts and other journal articles and background are online at [www.idahobirdobservatory.org](http://www.idahobirdobservatory.org).

Some of this year's data were included in the Raptor Population Index Project's 2008 report, "The State of North America's Birds of Prey." Such exposure distinguishes the science supported by IBO, but Kaltenecker said outreach is paramount.

"The research is important," he said, "but it means nothing if the public doesn't understand what we're doing, why we're doing it and the results." — Erin Ryan

## Himalayan Mountains Focus of a New Study

With funding from the National Science Foundation (NSF), a Boise State geology professor is studying the forces responsible for creating the world's tallest mountains.

Matthew Kohn is the principal investigator on a \$274,969 NSF award to conduct research in the Himalayan Mountains of northwest India. Kohn and his research group are analyzing data

collected last fall during a three-week field trip to the region. Kohn plans to return to northwest India later this year for further studies.

The researchers are examining the effects of pressure and temperature in Himalayan mountain building and will compare rock samples collected in northwest India to samples collected in Nepal. The data will help identify how the continental crust deforms and will increase scientific understanding of how the mountains developed.

India's Yamuna Valley is among Kohn's research sites.
